EDBT Summer school 2019 tutorial

September 6, 2019

## tutorial website

`https://rozensp.github.io/temporal-networks-tutorial`

# agenda

Part I : introduction and motivation

Part II : models of temporal networks

Part III : algorithmic frameworks

Part IV : data mining problems

Part V : future challenges

part I

introduction and motivation

# interconnected world

- networks model **objects** and their **relations**
- many different **network types**
  - social
  - informational
  - technological
  - biological
  - ...

# impact of network science

- online communication networks and social media
- implications in
  - knowledge creation
  - information sharing
  - education
  - democracy
  - society as a whole

# research questions in network science

- structure discovery
  - communities, summarization, events, role mining
- study complex dynamic phenomena
  - evolution, information diffusion, opinion formation, structural prediction
- develop novel applications
- design efficient algorithms

## traditional view

- networks represented as pure graph-theory objects  
no additional vertex / edge information
- emphasis on **static networks**
- **dynamic** settings model **structural changes**  
vertex / edge additions / deletions

# temporal networks

- ability to collect and store large volumes of network data
- available data have **fine granularity**
- lots of **additional information** associated to vertices/edges
- network topology is **relatively stable**, while lots of **activity** and **interaction** is taking place
- giving rise to **new concepts**, **new problems**, and **new computational challenges**

# modeling activity in networks

1. network nodes **perform actions** (e.g., posting messages)

2. network nodes **interact** with each other (e.g., a "like", a repost, or sending a message to each other)

# many novel and interesting concepts

new pattern types

temporal information paths

new types of events

network evolution

## temporal networks — objectives

- identify new concepts and new problems
- develop algorithmic solutions
- demonstrate relevance to real-world applications

# terminology

- we use term “temporal networks”, but terminology is not standardized
- term “X Y” can be encountered in the literature, where

X:

temporal  
dynamic  
(time-)evolving  
time-varying  
time-dependent  
evolutionary

Y:

networks  
graphs

- some combinations have distinct meaning, but not always

# examples of temporal networks

[Holme, 2015]

- **human communication networks**
  - phone, email, text messages, etc.
- **human proximity networks**
  - recorded by various sensors and devices, e.g., bluetooth, wifi, etc.
  - patient-referral networks, i.e., how patients are transferred between wards of a hospital system
  - sexual contact networks
- **animal proximity networks**
  - obtained via RFID devices
  - livestock or wildlife

# examples of temporal networks — cnt'd

[Holme, 2015]

- **bibliographic networks**
  - collaboration and citation networks
- **economic networks**
  - credit card transactions
  - trade networks of countries
  - bitcoin transactions
- **travel and transportation networks**
  - airline connections, bus transport, bike-sharing systems

# examples of temporal networks — cnt'd

[Holme, 2015]

- **brain networks**
  - temporal correlations of the oxygen levels of brain regions as measured by fMRI scanning
- **biological networks**
  - genes involved in different interactions that change over time
  - current challenges, as one cannot measure precisely when two proteins interact with each other, but technology is improving

# agenda

Part I : introduction and motivation

Part II : models of temporal networks

Part III : algorithmic frameworks

Part IV : data mining problems

Part V : future challenges

part II

models of temporal networks

# representation of temporal networks

## 1. sequence of interactions

- a temporal network is represented as  $G = (V, E)$ 
  - with set of nodes  $V$ , and  
set of edges  $E = \{(u, v, t)\}$ , with  $u, v \in V$  and  $t \in \mathbb{R}$
  - if interactions have duration, then  $E = \{(u, v, t, \lambda)\}$
- this is a lossless representation — no information is lost
- also known as sequence of contacts, or sequence of (temporal) edges

# representation of temporal networks

## 1. sequence of interactions

- visual representation of a temporal network as a sequence of interactions

# representation of temporal networks

## 2. sequence of static graphs

- sequence  $G_1, \dots, G_T$   
where  $G_t = (V_t, E_t)$ , with  $t = 1, \dots, T$   
typically assume that nodes are fixed, i.e.,  $V_t = V$   
 $E_t$  are the edges that occur in **time interval  $t$**
- **advantages**: static graph analysis methods can be applied
- **disadvantages**: the representation assumes **quantization** into time intervals
  - thus, representation depends on quantization parameters, e.g., seconds, minutes, hours, days, etc.
  - **coarse resolution** may lead to **information loss**
  - **fine resolution** may lead to **sparse** (or even empty) static graphs

# representation of temporal networks

## 2. sequence of static graphs

- visual representation of a temporal network as a sequence of static graphs

# representation of temporal networks

## 3. time series of contacts

- a time-series for each pair of nodes in the network
- equivalent representation with sequence of interactions

## 4. tensor representation

- tensor representing node  $\times$  node  $\times$  time information
- can apply powerful tensor-algebra techniques
- a complication is that time is directed, while tensor algebra assumes that indices can be relabeled (breaking the time ordering)

# representation of temporal networks

[Casteigts et al., 2012]

5. **time-varying graphs** defined as  $G = (V, E, T, p, \lambda)$ ,

where

- $V$ : set of nodes
  - $E \subseteq V \times V$ : set of edges
  - $T$ : a time domain
  - $p: E \times T \rightarrow \{0, 1\}$ : a presence function
  - $\lambda: E \times T \rightarrow \mathbb{R}$ : a latency function
- general definition that can be used to model graph datasets in different applications
    - transportation networks, communication networks, social networks

# representation of temporal networks

## 6. stream graphs and link streams [Latapy et al., 2018]

- a formalization for modeling interactions over time
- a stream graph is defined as  $G = (T, V, W, E)$ , where
  - $T$ : a time domain
  - $V$ : a set of nodes
  - $W \subseteq T \times V$ : a set of temporal nodes
  - $E \subseteq T \times V \times V$ : a set of links

s.t.,  $(t, u, v) \in E$  implies  $(t, u) \in W$  and  $(t, v) \in W$
- formalization is **self-consistent**: relations between concepts are preserved
  - e.g., can define clustering coefficient using density
- formalization **generalizes** usual concepts of graph theory
  - e.g., line graphs, k-cores, cliques, density, centralities

# temporal networks vs. dynamic graphs

- **dynamic graphs** is a standard model typically studied in theoretical computer science
  - e.g., [Henzinger et al., 1999, Thorup, 2000]
- dynamic graphs are represented as a **sequence** of **edge additions** and/or **edge deletions**
- $G_0$  is the initial graph, and  $G_i$  is the graph resulting after the  $i$ -th edge addition/deletion operation
- **objective**: **efficient maintenance of graph properties**
  - e.g., connectivity, shortest paths, spanners, etc.

## temporal networks vs. dynamic graphs

- in dynamic-graph studies, the properties of interest refer to **individual graph snapshots**  $G_i$ , not considering the whole **graph evolution**
- emphasis on **computational efficiency**
  - computation time **per operation**
  - e.g., cost of maintaining a minimum spanning tree per edge additions/deletions
  - or, cost of maintaining a data structure that allows to answer short-path queries
- **dynamic graph** model captures **topological changes**, not interactions
  - e.g., dynamic graphs can be used to model friendship additions/deletions in a social network, but not discussions or other interactions

# temporal networks vs. dynamic graphs

- **dynamic graphs** resemble **sequence of interactions** model
- main difference lies on which **graph properties** we study
- for dynamic graphs we typically consider **properties on graph snapshots**
  - i.e., minimum spanning tree on the current snapshot
- for temporal graphs we typically consider **properties that span a time interval**
  - i.e., a temporal pattern
- **disclaimer:** in this tutorial we **do not consider** dynamic graphs
  - however, it is a well-developed area with rich literature

# dynamic networks

- in the context of **graph generation models**, we consider **dynamic networks**
  - e.g., Barabási-Albert, forest-fire, copying model, etc.
- similar to **dynamic graphs**, as data are seen as a sequence of node/edge additions (typically no deletions)
- node/edge addition are governed by a **probabilistic model**, not arbitrary, or worst case, as in algorithmic models
- emphasis again on **network topology**, i.e., how certain **network structures emerge**
  - e.g., scale-free distribution, small world, etc.
- **disclaimer**: in this tutorial we **do not consider** dynamic networks

# graph streams

- setting inspired by **data streams**  
[Muthukrishnan et al., 2005]
- **recall** the **data-stream model**:
  - data are presented as a **sequence of data items** (potentially infinite)
  - assume a **small number of passes** typically constant or just one pass
  - assume **small memory** compared to data size e.g., poly-logarithmic
  - assume **fast computation** per data item processed e.g., constant or poly-logarithmic

# graph streams

- a **graph stream** is a **graph dataset** in the **data-stream model**  
e.g., sequence of interactions (temporal network), or  
sequence of edge additions/deletions (dynamic graph)
- thus, a graph stream is **not** a **representation model**, instead  
it refers to the underlying **computational model**
- thus, we can study questions of mining temporal networks  
in the graph-stream model

# dynamic graph algorithms on streaming model

- well-studied model
- extensive survey [McGregor, 2014]
- different settings considered
  - node/edge additions (**incremental**)
  - node/edge additions/deletions (**fully-dynamic**)
  - updating weights/labels is a special case of the fully-dynamic model
  - **sliding-window setting**: consider only edges from latest interval of fixed length
  - algorithms can be **deterministic** or **randomized**

# time-respecting paths

- a **fundamental concept** in analysis of temporal networks
  - used in studies of **information propagation**, or **epidemics spreading**
- a **time-respecting path** is a **sequence of temporal edges**, such that
  - consecutive edges **share a common node**, and
  - time stamps of temporal edges are **non-decreasing**
- intuitively, a piece of information (or disease) can propagate in the network **only** over **time-respecting paths**

## time-respecting paths — example

$(c, e, 2), (e, d, 5), (d, b, 6)$  is a time-respecting path from *e* to *b*

$(c, b, 3), (b, a, 1)$  is not a time-respecting path

# static expansion of a temporal network

- a transformation of a temporal network to a directed (static) network so that time-respecting paths in the temporal network correspond to directed (static) paths in the directed (static) network
- how to create such a transformation?

# static expansion of a temporal network

- a transformation of a temporal network to a directed (static) network so that time-respecting paths in the temporal network correspond to directed (static) paths in the directed (static) network
- how to create such a transformation?
  1. create a copy of each node for each time instance
  2. create a directed edge from the  $(t - 1)$ -th copy of  $u$  to the  $t$ -th copy of  $u$ , for all nodes  $u$ , and all time instances  $t$
  3. create directed edges for the temporal edges

# static expansion of a temporal network

example

(a) representation of a temporal network

(b) static expansion of temporal network

# static expansion of a temporal network

## example

(a) representation of a temporal network

(b) static expansion of temporal network; **directed edges**

# static expansion of a temporal network

## example

(a) representation of a temporal network

(b) static expansion of temporal network; **delays**

# reachability, connectivity, and connected components

- defined as in static graphs, but using **time-respecting paths**
- **reachability** :
  - used to study **infection spreading** and **information cascades**
- **connectivity** : as in directed (static) graphs is not symmetric
  - distinguish **strong** and **weak** connectivity
  - in addition, we can define **transitive connectivity**:  
a subgraph is transitively connected if time-respecting paths from  $u$  to  $v$  and  $v$  to  $w$  imply a time-respecting path from  $u$  to  $w$

# minimum temporal paths

different notions of **minimum temporal paths** rely on **time-respecting paths**

- **earliest-arrival path** : a path from  $x$  to  $y$  with earliest arrival time
- **latest-departure path** : a path from  $x$  to  $y$  with latest departure time
- **fastest path** : path from  $x$  to  $y$  with minimum elapsed time
- **shortest path** : fastest path from  $x$  to  $y$  in terms of overall traversal time required on edges

[Wu et al., 2014]

# diameter, network efficiency

- **diameter**: shortest latency of time-respecting paths over connected pairs [Chaintreau et al., 2007]
  - restricted on connected pairs, as real data have many disconnected pairs
- **network efficiency**: the harmonic mean of latency over all pairs [Tang et al., 2009]
  - **discussion**: what is the motivation for **harmonic mean**?

## diameter, network efficiency

- **diameter**: shortest latency of time-respecting paths over connected pairs [Chaintreau et al., 2007]
  - restricted on connected pairs, as real data have many disconnected pairs
- **network efficiency**: the harmonic mean of latency over all pairs [Tang et al., 2009]
  - **discussion**: what is the motivation for **harmonic mean**?
  - it combines average latency and reachability ratio

# centrality measures

- many centrality measures on static graphs use distances
- **closeness centrality** :  $C_c(u) = \frac{n-1}{\sum_{v \neq u} d(u,v)}$
- **betweenness centrality** :  $C_b(u) = \frac{\sum_{v \neq u \neq w} p_u(v,w)}{\sum_{v \neq u \neq w} p(v,w)}$
- for temporal networks we replace distance with shortest latency time-respecting path
- analogues of **Katz centrality** and **PageRank** have also been defined
- **discussion** : how do these centrality measures on temporal networks compare with their static analogues?

# temporal motifs

- temporal motif counting

[Paranjape et al., 2017, Kovanen et al., 2013]:

- temporal motif is a **small subgraph** with **temporally ordered** edges (and/or interval or delay constraints)

# temporal motifs

$\delta$ -temporal motif: a sequence of directed temporally ordered edges which appear within a time window  $\delta$

[Paranjape et al., 2017]

# agenda

Part I : introduction and motivation

Part II : models of temporal networks

Part III : algorithmic frameworks

Part IV : data mining problems

Part V : future challenges

part III

algorithmic frameworks for temporal network  
analysis

# frameworks

adopted traditional frameworks

- static expansion graphs
- dynamic graphs
- time-series
- labeled graphs

# static expansion graphs

- static graph of **time-stamped** nodes and **time-forwarding** edges  $G_e = (V_e, E_e)$
- $V_e = \{(v, t) \mid v \in V, t \in T\}$ , where  $T$  is the set of all possible timestamps
- edges  $E_e$ : interactions between the temporal nodes  $V_t$

# static expansion graphs

- static expansion graph is a **directed acyclic graph (DAG)**
- **standard graph algorithms** (BFS, DFS, Dijkstra, Bellman-Ford) can be adopted for finding:
  - **fastest temporal paths**,  
**shortest temporal paths**, and  
**weighted combinations**
  - journeys and walks
- **upstream**, **downstream** reachability sets

## time-respecting paths

( a ) Temporal Graph

( b ) Static Graph

- some paths in the static graph **are not meaningful** in the temporal graph
- e.g.,  $a-b-g-j$  is not time-respecting path
- what is the shortest path from  $a$  to  $l$ ?

# minimum temporal paths

different notions of **minimum temporal paths** rely on **time-respecting paths**

- **earliest-arrival path** : a path from  $x$  to  $y$  with earliest arrival time
- **latest-departure path** : a path from  $x$  to  $y$  with latest departure time
- **fastest path** : path from  $x$  to  $y$  with minimum elapsed time
- **shortest path** : fastest path from  $x$  to  $y$  in terms of overall traversal time required on edges

[Wu et al., 2014]

## earliest-arrival path

- temporal graph  $G = (V, E)$
- source vertex  $x$ , starting time  $t_s$
- array  $T$  of size  $|V|$  to record arrival times to each node
- $T[x] = t_s$  and  $T[v] = \infty$ , for nodes other than source
- process edges  $(u, v, t, \lambda)$  in temporal order
  - if  $t \geq T[u]$  ( $u$  is already reached from  $x$ )
  - check if the edge creates the earliest-seen-so-far path from  $x$  to  $v$  and update  $T[v]$ :  
 $T[v] = \min(T[v], t + \lambda)$

## latest-departure path

- temporal graph  $G = (V, E)$
- sink vertex  $x$ , ending time  $t_s$
- same process as for earliest-arrival path, but
- process edges in reversed temporal order
- add new interaction to the path if it does not violate temporal order

[Wu et al., 2014]

# minimum spanning trees

- $MST_a$ : minimum spanning tree with earliest-arrival times  
each temporal path from the root to the node is the earliest arrival path
- $MST_w$ : minimum spanning tree with smallest total weight  
or with the smallest number of hops: directed Steiner tree.

[Huang et al., 2015]

# applications of temporal paths

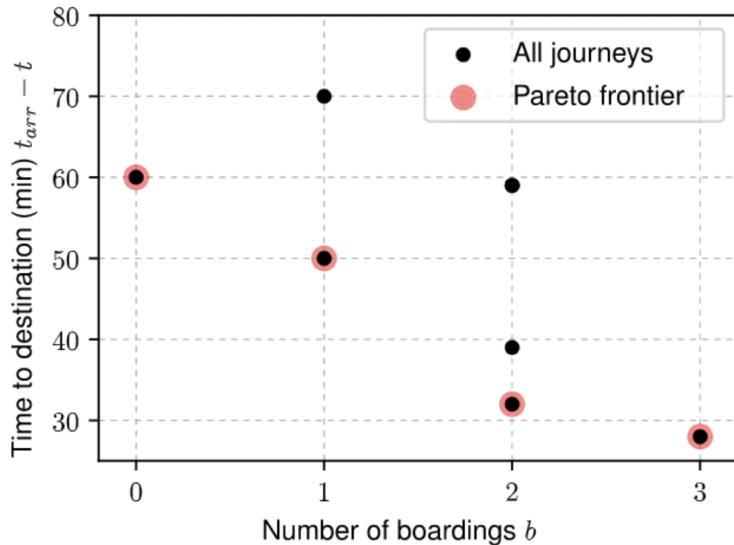

- temporal reachability problems
  - diffusion simulation, centrality measures
- directed spanning or Steiner trees
  - reconstruction of diffusion
- **drawback**: large size of expansion graph may lead to high computational complexity and large memory consumption
- **challenge**: **scalable algorithms** and **approximations**

# applications — transportation temporal networks

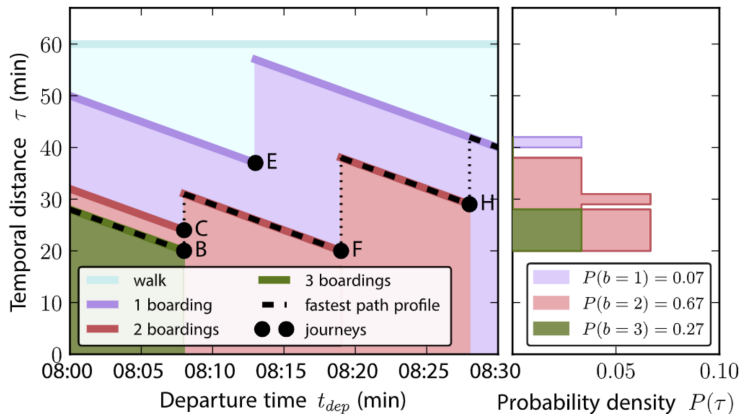

[Kujala et al., 2018]

## Pareto-optimal journeys

# Boarding-count-augmented temporal-distance profiles

(a) Boarding-count-augmented fastest-path temporal distance profile

(b) Boarding-count-augmented fastest-path temporal distance distribution

# dynamic graph algorithms on streaming model

- well-studied model
- extensive survey [McGregor, 2014]
- different settings considered
  - node/edge additions (**incremental**)
  - node/edge additions/deletions (**fully-dynamic**)
  - updating weights/labels is a special case of the fully-dynamic model
  - **sliding-window setting**: consider only edges from latest interval of fixed length
  - algorithms can be **deterministic** or **randomized**

# dynamic graph algorithms on streaming model

[McGregor, 2014]

	Insert-Only	Insert-Delete	Sliding Window (width $w$ )
Connectivity	Deterministic [27]	Randomized [5]	Deterministic [22]
Bipartiteness	Deterministic [27]	Randomized [5]	Deterministic [22]
Cut Sparsifier	Deterministic [2, 8]	Randomized [6, 31]	Randomized [22]
Spectral Sparsifier	Deterministic [8, 46]	Randomized $\tilde{O}(n^{5/3})$ space [7]	Randomized $\tilde{O}(n^{5/3})$ space [22]
$(2t - 1)$ -Spanners	$O(n^{1+1/t})$ space [11, 23]	Only multiple pass results known [6]	$O(\sqrt{wn^{(1+1/t)}})$ space [22]
Min. Spanning Tree	Exact [27]	$(1 + \epsilon)$ -approx. [5] Exact in $O(\log n)$ passes [5]	$(1 + \epsilon)$ -approx. [22]
Unweighted Matching	2-approx. [27] 1.58 lower bound [42]	Only multiple pass results known [3, 4]	$(3 + \epsilon)$ -approx. [22]
Weighted Matching	4.911-approx. [25]	Only multiple pass results known [3, 4]	9.027-approx. [22]

**Table 1: Single-Pass, Semi-Streaming Results: Algorithms use  $O(n \text{ polylog } n)$  space unless noted otherwise.**

# sliding-window neighborhood profiles

- temporal network  $G = (V, E)$
- stream of edges  $E = \langle (u_1, v_1, t_1), (u_2, v_2, t_2), \dots \rangle$   
with  $t_1 \leq t_2 \leq \dots$
- sliding window length  $w$
- snapshot network  $G(t, w)$  at time  $t$  contains all edges  
with time-stamps in  $(t - w, t]$

## problem :

given node  $u$ , window length  $w$ , and distance  $r$ , how many nodes in  $G(t, w)$  are within distance  $r$  from  $u$  at time  $t$ ?

[Kumar et al., 2015]

# empirical evaluation — running time

(c) Higgs

(d) DBLP

## contrast (DBLP)

- offline HyperANF : 3.6 sec / sliding window
- proposed approach : 0.003 sec / sliding window

[Kumar et al., 2015]

# time-series analysis

- view a temporal network as a (multivariate) time series
  - calculate temporal profile of nodes, edges, or a whole network
  - calculate distance between adjacent snapshots and analyze the resulting time series
- distance: edit distance, node-profile distances, vector-space distance
- applications in change-point detection, anomaly detection, evolutionary pattern mining

# event detection in time series

- given a sequence of graphs  $G_t$
- a function to calculate the vertex affinity matrix  $S$ , where  $s_{ij}$  indicates the influence vertex  $i$  has on vertex  $j$
- a set of time points for detected events is  $\{t \in T \mid d(G_t, G_{t+1}) \geq \delta\}$

where

$$d(G_t, G_{t+1}) = \sqrt{\sum_{i=1}^n \sum_{j=1}^n (\sqrt{S_{t,ij}} - \sqrt{S_{t+1,ij}})^2}$$

# time-series analysis

- anomaly detection survey [Ranshous et al., 2015]
- approach does not solve all the problems, as it does not capture the network topology
- **possible work-around**: use more topology embeddings metrics (larger neighborhoods, influence measures, eigenvectors, . . .)

# labeled graphs

- edges are **labeled** with **occurrence timestamps**
- applications of classic graph-theoretical problems
  - coloring, routing, network flow, covering, etc.
- “**any** property of a graph labeled from a discrete set of labels **corresponds** to some temporal property if interpreted **appropriately**” [Michail, 2016]

# labeled graphs

- for example, consider a **proper edge coloring**
  - a coloring of the edges in which no two adjacent edges share a common color
- corresponds to a temporal network where no two adjacent edges share a common time-label
  - i.e., no two adjacent edges ever appear at the same time
- **limitation**: labels are independent, timestamps are not

# theoretical aspects of temporal graphs

- how is the complexity of classic combinatorial optimization problems changes when time is added?
  - some old results: the **max-flow min-cut theorem** holds with **unit capacities** for **time-respecting paths** [Berman, 1996]
  - a number of recent attempts
    - sliding window **vertex cover** [Akrida et al., 2018]
    - sliding window **graph coloring** [Mertzios et al., 2018]
    - **maximal matching** [Mertzios et al., 2019]
- etc.

# theoretical aspects of temporal graphs

- there are many models for **abstracting** temporal networks
- **challenge**: which models are most general and most useful?

# agenda

Part I : introduction and motivation

Part II : models of temporal networks

Part III : algorithmic frameworks

Part IV : data mining problems

Part V : future challenges

part V

data mining problems

# data mining problems

- community detection
- event detection
- finding important nodes
- epidemics analysis and influence spreading
- network summarization
- ...

community detection

# community detection in static graphs

- static graphs: extensive survey [Fortunato and Hric, 2016]
- standard community definitions
  - a community is a set of nodes, which are closer to each other than to the rest of the network
  - a community is a dense network subgraph
- general definition [Coscia et al., 2011]
  - a community in a complex network is a set of entities that share some closely correlated sets of actions with the other entities of the community
- typical problem settings
  - a single community vs. network partition
  - overlapping vs. non-overlapping communities

# community detection in static graphs

## partition measures

- **modularity** : the difference between the actual number of edges and the expected
- **cut** : number of edges between a community and the rest of the graph
- **ratio cut** : cut normalized by the number of edges of community nodes
- ...

## single-community measures

- **average degree** :  $\frac{|E(S)|}{2|S|}$
- **density** :  $\frac{2|E(S)|}{|S|(|S|-1)}$
- **conductance** :  $\frac{cut(S, \bar{S})}{\min\{vol(S), vol(\bar{S})\}}$
- ...

# community detection in temporal networks

temporal information gives rise to several issues

- **temporal localization**: concise time interval or intervals, whole time history
- **behaviour**: single-appearance, recurring, persistent, evolutionary patterns, smoothness
- partition of the **topology network** vs. partition of the **time history**
- **online** vs. **offline**
- application-specific settings

# community detection in temporal networks

- proposed taxonomies
  - [Aynaud et al., 2013]
  - [Aggarwal and Subbian, 2014]
  - [Enugala et al., 2015]
  - [Renaud and Naoki, 2016]
  - [Hartmann et al., 2016]
  - [Rossetti and Cazabet, 2018]
  - [Dakiche et al., 2019]
  - ...

# temporal communities : temporal assumptions

**prior model**, which describes what is the temporal behavior of interesting community structures, e.g.,

- small/large covering intervals of community interactions
- frequent patterns
- persistent patterns

# evolutionary patterns : vocabulary

evolutionary patterns of communities in the network

[Dakiche et al., 2019]

- birth
- death
- growth
- contraction
- merge
- split
- continue
- resurgence

# temporal communities: taxonomy

we follow a recent survey on community detection

[Dakiche et al., 2019]

- independent community detection and matching
  - first detect communities at each timestamp
  - then match them across different timestamps

# independent community detection and matching

(1) A dynamic network consisting of three snapshots

(2) Community detection in each snapshot

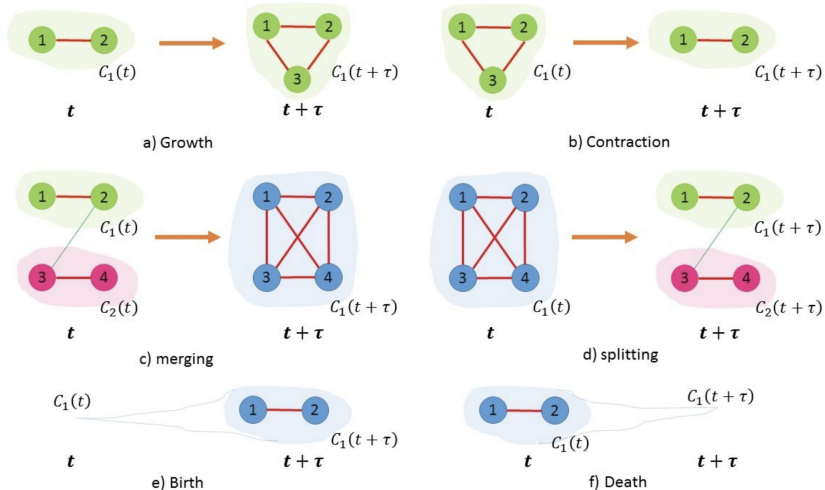

(3) Match communities of  $t$  and  $t+1$

(4) Match communities of  $t+1$  and  $t+2$

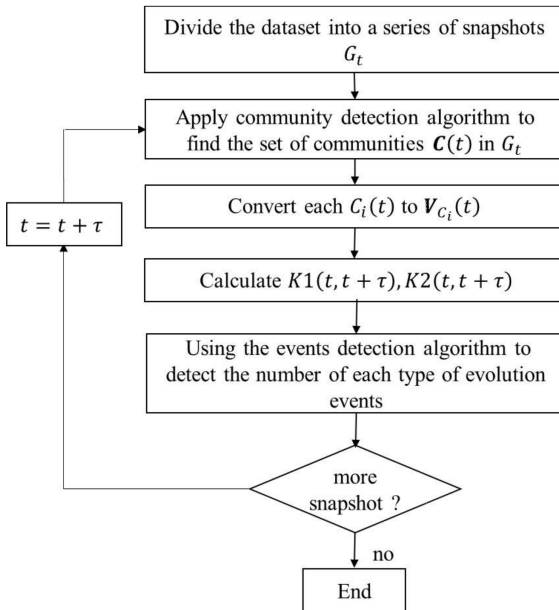

# typical evolutionary patterns

# procedure

# independent community detection and matching

## advantages

- reuses unmodified traditional community detection methods
- possible to use existing similarity measures

## disadvantages

- instability of community-detection algorithms

# temporal communities: taxonomy

[Dakiche et al., 2019]

- dependent community detection

detect communities at time  $t$  based on

- network topology at  $t$ , and
- communities at time  $t - 1$

# dependent community detection

(1) A dynamic network consisting of three snapshots

(2) Community detection in the first snapshot

(3) Community detection at  $t+1$  using graph of  $t+1$  and communities of  $t$

(4) Community detection at  $t+2$  using graph of  $t+2$  and communities of  $t+1$

# Louvain algorithm

- a fast greedy approach based on modularity optimization
- two phases repeated iteratively
  - initially, each node in network is a community
  - then, for each node  $i$ , consider its neighbor  $j$  and compute the gain of modularity of putting  $i$  into the community of  $j$
  - node  $i$  is placed into the community with the largest gain, if the gain is positive

[Blondel et al., 2008]

# Louvain algorithm

- on the **second phase**, each community is considered as a super-node
  - the edges between these super-nodes are contracted and re-weighted by the number of edges between them
- the two phases are repeated until there is **no improvement** in modularity
- the algorithm is **extremely fast**

[Blondel et al., 2008]

# history-dependent approach

## idea

- for two consecutive time steps, there only few edges that affect the community structure
- if the connections of all the nodes in the same community at time step  $t - 1$  keep unchanged at time step  $t$ , they are still in the same community at time step  $t$
- thus, no need to break that super-node

[He and Chen, 2015]

# history-dependent approach

- find all communities in snapshot  $t = 1$
- for  $t = 2$ :
  - if a node's connection change, then remove it from its super-node and add as single node
  - leave all other nodes inside the super-node
  - re-weight the edges

# dependent community detection

## advantages

- a solution for the problem of instability
- improved computational complexity

## disadvantages

- traditional community detection methods are no longer directly applicable

# temporal communities: taxonomy

[Dakiche et al., 2019]

## simultaneous community detection on all snapshots

- construct a **static expansion graph**
  - add edges between instances of nodes in different timestamps
- run a standard community detection on the resulting graph

# simultaneous community detection on all snapshots

(1) A dynamic network consisting of three snapshots

(2) Community detection on all snapshots

[Dakiche et al., 2019]

# simultaneous community detection

- algorithm based on some basic **assumptions** about **individual behavior** and **group membership**

## assumptions

- **gradual changes** : nodes change community affiliation infrequently
- **reliable true positive** : members of the same community mostly interact with each other
- **negligible false positive** : members of different communities rarely interact with each other

[Tantipathananandh and Berger-Wolf, 2011]

# simultaneous community detection

## costs

- **switching cost**: each node  $u$  incurs cost  $C_{sw}$  when changing community affiliation
- **false negative cost**: two nodes incur cost  $C_{fn}$  when belong to the same community but do not interact
- **false positive cost**: two nodes incur cost  $C_{fp}$  when belong to different communities but do interact

## resulting problem

- find a partition into clusters that **minimizes** the total cost of switching, false negative, and false positive

[Tantipathananandh and Berger-Wolf, 2011]

# simultaneous community detection

$$(C_{sw}, C_{fn}, C_{fp}) = (5, 1, 5) \text{ vs. } (C_{sw}, C_{fn}, C_{fp}) = (1, 1, 5)$$

# simultaneous community detection on all snapshots

## advantages

- provides a solution for the problem of instability

## disadvantages

- no possibility to track community evolution in a network evolving in real time

# temporal communities: taxonomy

[Dakiche et al., 2019]

## dynamic community detection

- update previously discovered communities according to network modifications

# dynamic community detection

(1) Temporal network: an initial snapshot and sequence of modifications

(2) Community detection on first snapshot

(3) Update communities of  $t$  according to modifications of  $t+1$

(4) Update communities of  $t+1$  according to modifications of  $t+2$

# dynamic community detection

## advantages

- provides a solution for the problem of instability
- light-weight methods to track communities

## disadvantages

- possibility to drift towards invalid communities

event detection

## event detection

- given a network representing some kind of activity
  - network of social interactions
  - social-media feed
  - transportation network
- an event can be generally defined as an activity with some prominent **qualitative** or **quantitative difference** from the **background activity**
  - bursting news about major natural disasters
  - abnormally high traffic in the city
  - an emerging new discussion topic in social media

# applications

- **news spread** in social media faster than in traditional news media [Sakaki et al., 2010, Dou et al., 2012]
- **weather** or **traffic** condition warning systems
- early notification about **influential social events**
- understanding **causal relations**, semantics, and dynamics of what is happening

comprehensive survey on event detection in dynamic networks  
[Ranshous et al., 2015]

# temporal event detection

- identify **atypical time intervals** and/or **time instances**
- temporal records
  - time sequences (time-ordered records) or
  - time series (equally-spaced in time sequences)
- number of interactions, tweets, reposts, purchases, check-ins, or some other measures in absolute values or aggregated per time unit

# temporal event detection

- time series may represent a temporal network
  - **topological** characteristics of each snapshot
  - **distance** between two consecutive graph snapshots

# temporal event detection: standard approaches

## abnormality score

- the likelihood that an interval contains an event can be estimated by comparing an abnormality score on the interval

[Heins and Stern, 2014]

## predictive models

- learn a predictive model and find intervals and time points whose behavior differ from the predicted one

[Hunter and McIntosh, 1999, Gensler and Sick, 2017]

# Netsimile

- an event exists in  $G_{j+1}$ , if  $G_{j+1}$  is very different than  $G_j$
- for each node calculate 7 local and egonet-based measures
  - degree
  - clustering coefficient
  - average degree of neighbours
  - average clustering coefficient of neighbours
  - number of edges in the egonet
  - number of edges outgoing from the egonet
  - number of neighbours of the egonet
- combine into a signature vector and compare

# Netsimile algorithm

(a) NetSimile between each day and day 0 in Yahoo! IM

# spatiotemporal event detection

detailed survey [Shi and Pun-Cheng, 2019]

- consider time and the (geo-)location of an event
- **sources** of spatial data
  - GPS devices / smart phones
  - geo-tagged messages in online social networks
- typical approaches model the data as a set of geo-locations associated with **activity measurements**
- given a set of **locations** with activity measures, find a subset of locations that are **close** to each other and have **abnormal** activity pattern
- in **spatiotemporal** setting, one is also interested in finding the **time** interval (moment) of an event

# spatiotemporal event detection: scan statistics

- a classic family of methods is **spatial** and **spatiotemporal scan statistics**
- **scan** over the **space** and **time** windows to identify regions of data generated by some process

# spatiotemporal event detection: scan statistics

- a seminal paper : **spatial scan statistics** [Kulldorff, 1997]
- scan a circular spatial window and test the non-randomness of data against Poisson or Bernoulli baseline process

[Takahashi et al., 2004]

# spatiotemporal event detection: scan statistics

- later the approach was extended to **spatiotemporal** scans with **cylindric** windows
- similar works explore **other types** of statistics and tests [Neill, 2006, Qian et al., 2014].

[Takahashi et al., 2004]

## flexible scans

- flexible spatial scan-statistics
- first, divide the entire area into many small regions
  - the location of each region is the administrative population centroid
- next, the set of irregularly shaped windows: concentric circles and connected regions
  - $k$  is a pre-specified maximum length of cluster
- similar idea is used in the flexible space-time scan statistics
- both of these are fitted to a small cluster size

[Takahashi et al., 2008]

# flexible scans

simulated disease maps in the Tokyo Metropolitan area

(c) Respiratory (flexible on Aug.12)

(d) Respiratory (flexible on Aug.15)

[Takahashi et al., 2008]

# structural event

- **structural** event:
  - set of **interconnected** abnormal **nodes**
  - **no assumptions** on geodesic distances
- e.g., the edge weights represent **similarity** of nodes
  - similarities between twitter users in preferences, language, frequently visited locations, etc.
- scan **extension** to graph model [Liu et al., 2016b]
- scan through a graph **neighborhood** — a set of interconnected nodes
- **dense subgraph** detection
  - e.g., [Charikar, 2000, Khuller and Saha, 2009]

# semantic event detection

- define event as an **emerging/bursting/unusual** topic in social media, or
- use **textual** information to supplement and support event detection
  - **meaning** of the event
  - more **robust** event detection
- simplest use of textual information monitor the **frequencies** of separate **key words** [Lappas et al., 2012]
- efficient for **predefined** events, vocabulary is known
- more **general** approach: topic modeling to identify the event vocabulary
- combine with **other** event-related information
  - e.g., the geo-tags of tweets

[Hong et al., 2012, Kling et al., 2014]

# ETree

- aggregate **semantically similar** (based on  $n$ -grams) tweets into information blocks
- model an event in twitter as a **tree** of **information hierarchy**, where nodes are subtopics
- each subtopic is a directed graph of **information blocks**, where edges are potential causal relationships
- the causal estimates rely on content **similarity** and **temporal** relevance
- **assemble** a topic tree by greedy heuristic

[Gu et al., 2011]

finding important nodes

# PageRank

- classic approach for measuring **node importance**
- listed in the **top-10 most important data-mining algorithms**

[Wu et al., 2008]

- numerous applications
  - ranking web pages
  - trust and distrust computation
  - finding experts in social networks
  - ...

# static PageRank

- graph  $G = (V, E)$
- corresponding row-stochastic matrix  $P \in \mathbb{R}^{n \times n}$
- personalization vector  $\mathbf{h} \in \mathbb{R}^n$
- PageRank is the **stationary distribution** of a random walk, with restart probability  $(1 - \alpha)$

$$\pi(u) = \sum_{v \in V} \sum_{k=0}^{\infty} (1 - \alpha) \alpha^k \sum_{\substack{z \in \mathcal{Z}(v, u) \\ |z|=k}} h(v) \Pr[z | v]$$

where,  $\mathcal{Z}(v, u)$  is the set of all paths from  $v$  to  $u$

and  $\Pr[z | v] = \prod_{(i,j) \in z} P(i, j)$

# motivating example

(a)

static network

(b)

temporal network

(c)

temporal network

# temporal PageRank

- make a random walk only on **temporal paths**  
e.g., **time-respecting paths**  
time-stamps increase along the path

$c \rightarrow b \rightarrow a \rightarrow c$  : time respecting

$a \rightarrow c \rightarrow b \rightarrow a$  : **not** time respecting

# temporal PageRank

- **intuition** : probability of visiting node  $u$  at time  $t$  given a random walk on temporal paths
- need to model probability of following next temporal edge
  - we use an exponential distribution
- **temporal PageRank definition**

$$r(u, t) = \sum_{v \in V} \sum_{k=0}^t (1 - \alpha) \alpha^k \sum_{\substack{z \in \mathcal{Z}^T(v, u | t) \\ |z|=k}} \Pr'[z | t]$$

$\mathcal{Z}^T(v, u | t)$  set of temporal paths from  $v$  to  $u$  until time  $t$

# static vs. temporal PageRank

- computation:  
simple online algorithm iterating over edges
- temporal PageRank is designed to capture changes in network dynamics and concept drifts
- proposition :  
if the edge distribution is stable, then as  $T \rightarrow \infty$ , the temporal PageRank on  $G$  converges to the static PageRank on  $G_S$ , with personalization vector equal to weighted out-degree

[Rozenshtein and Gionis, 2016]

diffusion analysis and influence spreading

# diffusion analysis and influence spreading

- propagation models
  - used to study disease spreading or information cascade in the network
- activity spreading: virus, information, idea, rumor
- applications: epidemiology, information security, marketing
- why use models?
  - facilitate mathematical analysis of propagation processes
  - have intuitive interpretation
  - proven to be realistic by empirical studies
- extensive survey in the book [Shakarian et al., 2015]

# standard models

- susceptible-infected (SI) model
  - SIR, SIRS, other variants
- independent cascade (IC) model
- linear threshold (LT) model
- shortest path (SP) model

## static models: assumptions

- all models have similar implicit assumptions on temporality:
  1. uniform time steps
  2. interactions happen at each time step and are independent

## drawbacks of static models

- large **heterogeneity in the time instances** of real interactions

[Barabasi, 2005, Candia et al., 2008, Leskovec and Horvitz, 2008]

- **burstiness** in communication patterns
- **periodic** activity changes
- **causal** relationships between interactions

# temporal propagation models

- intuitive **extensions** from **static graphs** to temporal graphs
- add distributions (e.g., Poisson or power-law) of the **intervals between interactions** (latencies)

[Vazquez et al., 2007, Min et al., 2011]

- **realistic generalizations** of well-studied models

[Karsai et al., 2011, Candia et al., 2008]

- continuous time, partially observed graph
- develop **mathematical analysis** for novel and generalized models

[Harris, 2002, Fernández-Gracia et al., 2011]

# typical problem formulations

- immunization strategies
- influence maximization
- seed and cascade reconstruction

# static immunization strategies

- how to stop or prevent a viral diffusion?
- **main aspects** differentiating the research works:
  - assumptions about the **spreading model**
  - assumptions about the **network structure**
  - whether the whole network is **observable**
- **both** assumptions on the network **structure** and on the infection **propagation** are **crucial**
- results may not hold for any **general network** and **real** infection

[Newman, 2003, Pastor-Satorras and Vespignani, 2002a].

# static immunization strategies

- simple **model-blind strategies**, such as **random immunization**, perform moderately **well** in different scenarios

[Pastor-Satorras and Vespignani, 2002b, Madar et al., 2004]

- better results on real-world networks can be achieved by immunizing nodes with **high connectivity**

[Pastor-Satorras and Vespignani, 2002b, Dezső and Barabási, 2002].

- requires explicit **knowledge** of the **network structure** and it is **impractical** for real applications

## static immunization strategies

- [Cohen et al., 2003] overcomes this drawback by employing acquaintance immunization strategy:
- immunization of random neighbors of randomly selected nodes leads to immunization of the most central nodes without knowing any global information about the network

# temporal immunization strategies

- adjust successful static strategies
- e.g., Cohen's neighborhood vaccination scheme  
[Lee et al., 2012]
- two vaccination strategies
- recent :
  - ask a random individual  $i$  to name its most recent contact and vaccinate this person
- weight :
  - ask a random individual  $i$  to name its most frequent contact since some time  $t$

## 2 protocols

## static influence maximization

- how to select the **initial set** of infected nodes (**seeds**), such that the **speed**, **size**, or other **spread characteristics** are **optimized**
- applications in **marketing** and **network design**
- influence maximization problem was introduced by [Kempe et al., 2003] in the **IC** and **LT** models
- find a set of  $k$  **seed nodes**, such that the **expected number** of nodes activated by the infection cascade is **maximized**

# static influence maximization

- NP-hard [Kempe et al., 2003]
- simple greedy algorithm with approximation guarantee
- influence maximization problem was been studied for many different variants of other models, constraints, and objective functions
- many practical heuristics and approximations  
[Chen et al., 2009, Chen et al., 2010, Tang et al., 2014]

# temporal influence maximization

- **intuitive** approach to reflect temporality:
  - **sequence** of graphs (or snapshots)
  - each **time step** of propagation corresponds to propagation over the **corresponding graph**
  - all interactions within one time step happen **simultaneously**
- related papers:  
[Aggarwal et al., 2012, Zhuang et al., 2013, Gayraud et al., 2015]

# temporal influence maximization

- **another** approach:
- incorporate time into the diffusion model as **distribution of intervals** between the interactions
- different types of **models** and **interval distributions**

[Chen et al., 2012, Liu et al., 2012,  
Rodriguez and Schölkopf, 2012, Du et al., 2013]

- the most **realistic approachable** setting?
- the latest promising research:
  - **infer** propagation model parameters from the data

[Rodriguez et al., 2011, Gomez-Rodriguez et al., 2016]

# seed and cascade reconstruction

- given some **observed data** about the **infection**
  - e.g., a **small subset** of infected nodes,  
the goal is to find the **most probable seed nodes**
- other **versions**:
  - find the **most probable cascades**
- the **order** of infection (who got infected from whom)
- these works are **data-driven**:
  - it is essential that the **assumed** propagation model matches the **actual** infection flow in the network

# seed and cascade reconstruction

- applications:
  - epidemiology (who was the patient zero?)
  - influencer discovery  
(who was the source of information?)
- a number of different approaches
  - find a single source under the SI model  
[Shah and Zaman, 2011]
  - multiple seeds [Prakash et al., 2012]
  - $k$  seeds under the IC model [Lappas et al., 2010]
- the most recent papers
  - take advantage of the recorded infection order  
[Sefer and Kingsford, 2016].

# temporal reconstruction

- the problems formulated **in this setting** tend to be either
  - **oversimplified** versions of static reconstruction or
  - become **too hard** or **ill-posed**
- knowing the history of interactions allow to reconstruct feasible paths of infection and prune unfeasible
- any noise or missing information adds uncertainty
- need more assumptions about the **noise** and information **available**

# temporal reconstruction

- some problem formulations :
- reconstruct the cascade given the **sequence** of graph **snapshots** along with **node-status information**  
[Feizi et al., 2016, Sefer and Kingsford, 2016]
- reconstruct an **SI cascade** from one **sampled snapshot** with **all** information  
[Sundareisan et al., 2015]
- while there are methods to handle **partially observed cascade** for static graphs, in temporal graphs most of works rely on **noise-free data**
- the knowledge of the **diffusion model** is crucial
- see survey paper: [Holme, 2015]

# history reconstruction

network summarization

# network summarization

- aims to **simplify** and **explain** the **high-level** structure of complex real graphs
- many different problem formulations and techniques:
  - recent **survey** [Liu et al., 2016a]

# motivation and applications

- **fast** and **interactive** large-graph analysis:
  - summaries decrease **space** and **memory** required for the **storage** and **processing** of real-world networks
- clear human-understandable **visualization**
- **noise elimination**: **filter out** insignificant structural fluctuations in networks and **preserve** only prominent patterns

# approaches to summarization

- sparsification
- aggregation / compression
- non-graph summary

# sparsification

- remove somewhat **unimportant** edges or/and nodes
- preserving certain **local** or/and **global** structures
- important properties to preserve are **cuts**, **community structures**, **distances**, **spectral properties**, etc.

(a) Quadrilateral Simmelian Backbone

(b) Quadrilateral Simmelian Backbone with UMST

[Hamann et al., 2016]

# sparsification

- sparsification problems are often formulated as optimization problems:
  - minimize some kind of graph approximation (reconstruction) error
  - while sparsifying as much as possible
- another common approach are heuristic strategies
- survey: [Hamann et al., 2016]

## some comparison

- random edge (RE)
- triangle counts (Tri)
- Jaccard similarity (JS) [Satuluri et al., 2011]
- simmelian backbones (TS, QLS) [Nick et al., 2013]
- edge forest fire (EFF) [Leskovec and Faloutsos, 2006]
- algebraic distance (AD) [Chen and Safro, 2011]
- local degree (LD) [Hamann et al., 2016]
- “local” versions of all mentioned methods  
[Hamann et al., 2016]

[Hamann et al., 2016]

# some comparison

## aggregation / compression

- super graph:
  - nodes are grouped into **supernodes** and
  - edges between the super nodes form **superedges**
- graph aggregation can be formulated as an optimization problem
  - **minimizing reconstruction error**
  - **preserve some properties**
- common heuristic is to build a supergraph based on **clustering**

[Abello et al., 2006, Cléménçon et al., 2012]

# aggregation / compression

- some examples:
  - **node aggregation** to approximate **node degree** and **eigenvector centrality**  
[LeFevre and Terzi, 2010, Riondato et al., 2017]
  - **edge aggregation** to preserve the **weights of superedges** or **strengths of the paths**  
[Toivonen et al., 2011]

# compression example

- graph  $G = (V, E)$
- number  $k$
- $A_G$  : adjacency matrix of  $G$
- $k$ -summary  $S$  of  $G$  is a complete undirected weighted graph  $S = (V', V' \times V')$
- where  $V'$  is a disjoint  $k$ -partition of  $V$

## non-graph summary

- represent some **interesting**, **characterizing**, or otherwise **important** structures observed in the graph
    - e.g. a set of tightly interconnected nodes (**communities**)
    - graph can be summarized as a set of communities, **ignoring other parts**
- [Lancichinetti et al., 2011, Perozzi and Akoglu, 2018]

## non-graph summary

- other examples:
  - **motif** counting  
(counting small subgraphs of restricted size)  
[Itzhack et al., 2007]
  - finding **frequent** subgraphs  
[Jiang et al., 2013]
- other approaches develop **specialized vocabulary** to encode a large graph.
- e.g., summarize by a set of **chains**, **stars**, **cliques**, and **bipartite cores**  
[Koutra et al., 2015]
- this framework can be **further extended** to domain-specific vocabulary constructed by an expert

# vocabulary-based summarization

- **vocabulary**: full and near cliques (fc, nc), full and near bipartite cores (fb, nb), stars (st), and chains (ch)
- encode the graph using **MDL-base encoding**:  
**graph = vocabulary + noise**

- more approaches in the **survey** [Liu et al., 2016a]

[Koutra et al., 2015]

# temporal graph summarization

## adaptation of existing techniques

- **frequent subgraph mining**: find **persistent** graph patterns over a collection of snapshots
- do not take into account how the instances of the same subgraph are **located in time**
- **sequential pattern mining**: search for **time-ordered patterns** in the sequence of snapshots
- network **evolutionary patterns**  
[Berlingerio et al., 2009, Wackersreuther et al., 2010]
- ignores **structural patterns**
- **time-series analysis**: gather **node- and structure-dependent statistics** over time
- apply **segmentation** techniques [Ye and Keogh, 2009]
- does not consider **network structure**

# temporal techniques

- summarization of **both structural** and **temporal** aspects
- how to **define** a summary?
- many possible options:
  - a summary can be a **short temporal sequence** of small graphs,
  - a concise presentation of **evolutionary patterns**,
  - a representative collection of temporally and topologically **frequent patterns**
- one **common** approach to summary definition:
- summary should consist of
  - small structurally **“interesting”** subgraphs
  - with **non-trivial** temporal behavior

# temporal motifs

- temporal **motif counting**  
[Paranjape et al., 2017, Kovanen et al., 2013]:
  - temporal motif is a **small subgraph** with **temporally ordered** edges (and/or interval or delay constraints)
- some other works explore **temporal graphlets**
  - time constrained **causal subgraphs**  
[Hulovatyy et al., 2015]  
and cyclic patterns  
[Lahiri and Berger-Wolf, 2008]

# temporal motifs

$\delta$ -temporal motif: a sequence of directed temporally ordered edges which appear within a time window  $\delta$

[Paranjape et al., 2017]

# vocabulary-based summarization

- summarize a temporal graph as a **set**:
  - subgraphs of a special “most non-random” **shape** (**stars, cliques, bipartite cores, chains**), and
  - behavioural **temporal** patterns (**flickering, periodic, oneshot, ranged, and constant** patterns)
- use **MDL principle** to encode whole temporal network by the **vocabulary** plus **noise**

[Shah et al., 2015]

## larger structures

- use **larger structures** to summarize the network:
  - communities
  - spanning graphs
  - backbones
  - cores
- common approach:
  - given a **sequence** of graphs  
(snapshot, or sliding-window aggregation)
  - search for communities that are **coherent** and/or **persistent** in time
- different measures of community **quality** and temporal **smoothness** are used  
[Pietiläinen and Diot, 2012, He and Chen, 2015]
- the resulting summary is a **trade-off** between structural quality and historical consistency

# temporal backbones

# influence-based summarization

- summarizes the **flow of information propagation**:
  - find **influential** nodes and **information-forwarding** connections
- OSNet [Qu et al., 2014]:
  - processes a temporal network in a **streaming** fashion
  - outputs the subgraphs of **influential** nodes
  - node importance is calculated based on **temporal spreading trees**
- [Lin et al., 2008] identify **influential** nodes and **interactions** in temporal multi-view social networks
  - networks with edges between **different types of entities**, e.g., users, photos, and comments
  - explain the **evolution of topics** over time

# agenda

Part I : introduction and motivation

Part II : models of temporal networks

Part III : algorithmic frameworks

Part IV : data mining problems

Part V : future challenges

part V

future challenges

# temporal community detection: challenges

- large number of **problem formulations** and variants
- lack of **fundamental theoretical** treatment
  - most of the approaches are **heuristics**
  - many are combinations of **several** ideas and algorithms
  - require **many** parameters and attention to **implementation details**
- **hard to compare** methods and choose one for an application
  - **few datasets** with ground-truth temporal communities
  - synthetic generators are built on **various assumptions**
  - **no** standard benchmarks
- a large number of **quality metrics** to calculate and compare
- may be **misleading** if a method is not designed for that particular community definition

## event detection: challenges

- actively **evolving** area, **application-** and **data-oriented**
- families of problems and methods are considered only for the **specific** sources of data
  - e.g., a large body of research is focused on the analysis of **Twitter** data [Atefeh and Khreich, 2015]
- **no unified classification** for problem settings, research questions, and data requirements
  - recent classifications are based on **various** aspects:
  - event **definitions**, **online or retrospective** detection, **specified or unspecified** event detection, etc.  
[Cordeiro and Gama, 2016, Goswami and Kumar, 2016]

## event detection: more challenges

- **speed and quality:**
- **online streaming** event-detection techniques are demanded for **nearly real-time** event detection
- **quality:** both **false events** and **missed events** may have a high price
- more use of **multi-modal** data:
- **text:** complex semantic and sentiment analysis is rare
- high-resolution **interaction patterns:** “who talked to whom about what and what happened then” are also often not considered

# diffusion analysis: challenges

- **influence maximization** and **immunization strategies**:
  - what is the most **realistic approachable** setting?
- **models**:
  - temporal diffusion models are proposed, but the **theoretical properties** of many of them are **not yet well studied**
  - the applications and limitations are **not yet well understood**
- **immunization strategies**:
  - not extensively studied yet
  - most of the approaches are based on **heuristics**

## summarization: challenges

- **meaningful** summary vocabulary
- diversity of summarizing substructures is vast  
[Perozzi and Akoglu, 2018, Koutra et al., 2015, Jiang et al., 2013])
- which summaries are **preferable** and in which **applications**?
- summaries **useful** for a general network exploration by a **non-expert analyst**?

## summarization: more challenges

- fast and light-weighted algorithms
- interactive analysis
- have a hierarchical structure, which is possible to browse
  - similar to a visual analytic tool *OntoVis*, which constructs some type of graphical summaries  
[Shen et al., 2006]
- multi-level summarizations:
- use all available attributes in the temporal networks
  - text, geotags, propagation patterns...
